Abstract

We present ScaleOCR, a scalable framework for training vision-language models on document understanding tasks. Our approach combines a high-resolution image encoder with a large language model decoder, trained on a diverse corpus of 50 million annotated document pages spanning 84 languages and 12 document categories. ScaleOCR achieves state-of-the-art results on DocVQA (97.3), OmniDocBench (91.2), and the OCRBench benchmark suite, outperforming prior methods by 3.1 points on average. We further demonstrate that scaling model capacity and training data consistently improves performance, and release our model weights, training code, and evaluation suite to the research community.

1. Introduction

Optical character recognition has long been a cornerstone of document digitization. Recent advances in vision-language models (VLMs) have dramatically improved OCR quality on complex layouts, multilingual text, and handwriting.

2. Related Work

Early OCR systems relied on rule-based character segmentation and HMM-based recognition. CTC-based models improved performance on scene text. Transformer-based approaches

(Donut, TrOCR) demonstrated end-to-end document understanding.

3. Method

Our ScaleOCR architecture consists of three components: (1) a high-resolution SigLIP visual encoder that processes 4096×4096 images via dynamic tiling, (2) a cross-attention adapter projecting visual tokens to the LLM embedding space, and (3) a Qwen-2.5-7B decoder fine-tuned on document QA pairs.

4. Experiments

We evaluate on seven standard benchmarks. Table 1 shows our results. ScaleOCR achieves 97.3 on DocVQA, 91.2 on OmniDocBench, and 89.1 on OCRBench v2.
